

## Assignment 5

**After a weekend conference the new CEO has come back with new ideas. Thankfully you manage to talk down the blockchain idea, but their conviction remains that this project must become a web application.**

- Migrate your solution to ASP.NET core MVC. This should only affect your GUI. Add an ASP.NET Core Web App (Model-View-Controller), not the razor pages one. We will generate the crud for 1-2 entities at the seminar. For your architecture you have a couple of options:
  - Copy your service layer to the new project have it connect to your API through your existing proxy. In this case pay attention to update both copies if needed.
  - The same as the previous but put your service and proxy repository to a class library, then reference it from both desktop and web.
  - Change your API to expose your service instead of your repository. Have desktop and web use a service proxy instead.
  - The same as the previous but put your service, proxy service and repository to a class library, then reference it from both API and web. You can choose to call your API from the web or the service directly.
- By default, ASP.NET core MVC comes with jQuery and Bootstrap. If you want to use any extra javascript / css framework(s) you need to get the express approval of the other team in the project, and the client (at one of the courses).
- All functionalities need to be guarded from unauthorized users.
- Use a dependency injection framework for your project, have it do all the instantiations.
- Create a sequence diagram for a functionality (1/student, distinct from others, pick the most interesting scenario).
- You may use memory caches, just make sure they are cleared when appropriate.
- During your 6<sup>th</sup> seminar you will deploy your code to your server, if this comes before your demo at the 6<sup>th</sup> lab then redeploy your changes for the demo.

Deadline: lab 6
